## **Higher Category Theory**

## Assignment 10

## Exercise 1

*Proof.* (1) Denote by  $\mathcal{F}$  the class of maps being sent to bijections through  $\pi_0$ . Firstly we observe that  $\mathcal{F}$  is stable under retracts. Indeed, if  $f: K \to L$  is in  $\mathcal{F}$  and admits a retract  $g: X \to Y$ , then applying  $\pi_0$  yields a commutative diagram

$$\pi_0(X) \xrightarrow{s} \pi_0(K) \xrightarrow{p} \pi_0(X) 
\downarrow g_* \qquad \downarrow f_* \qquad \downarrow g_* 
\pi_0(Y) \xrightarrow{t} \pi_0(L) \xrightarrow{q} \pi_0(Y)$$

where ps = id, qt = id and  $f_*$  is a bijection. From  $pf_*^{-1}tg_* = ps = \text{id}$ , one gets that  $g_*$  is injective, while from  $g_*pf_*^{-1}t = qt = \text{id}$ , it follows that  $g_*$  is surjective. Hence  $g_*$  is a bijection, i.e.  $g \in \mathcal{F}$ .

Moreover, we claim that  $\mathcal{F}$  is closed under colimits, and hence under pushouts, coproducts and countable compositions. To this end, take any  $f_i \colon K_i \to L_i$  in  $\mathcal{F}$  indexed by a small category I. Since  $\pi_0$  is a left adjoint, we have  $\pi_0(\operatorname{colim}_I f_i) = \operatorname{colim}_I \pi_0(f_i)$  is a bijection and thus  $\operatorname{colim}_I f_i \in \mathcal{F}$ . Therefore  $\mathcal{F}$  is saturated.

(2) Recall that

$$(\Lambda_k^n)_i = \{ f : [i] \to [n] \mid \text{im}(f) \not\supseteq \{0, \dots, k-1, k+1, \dots, n\} \}$$

for any i. Hence it follows directly that  $(\Lambda_k^n)_i = \Delta_i^n$  for  $n \ge 2$  and i = 0, 1. Therefore  $\pi_0(\Lambda_k^n) = [\Delta^0, \Lambda_k^n] \cong [\Delta^0, \Delta^n] = \pi_0(\Delta^n)$  for  $n \ge 2$ . For n = 1 we have  $\Lambda_0^1 = \Lambda_1^1 = \Delta^0$  and  $\pi_0(\Lambda_k^1) = *$ , while by Exercise 1.1 of Sheet 9 we know that  $\pi_0(\Delta^n) = *$  for any n. Nevertheless, notice that this is not true for n = 0, as the 0-horn  $\Lambda_0^0 = \emptyset$  but  $\pi_0(\Delta^0) = *$ .

- (3) From (2) it follows that the inclusions  $\Lambda_k^n \hookrightarrow \Delta^n$  (for  $n \ge 1$  and  $0 \le k \le n$ ) are in  $\mathcal{F}$ . Hence by Gabriel-Zisman all anodyne extensions belong to  $\mathcal{F}$ .
  - (4) This follows immediately from (3) and a theorem in Lecture 17.
- (5) Recall that  $\pi_0$  has an alternative definition  $\pi_0(X) = \operatorname{colim}_{\Delta^{\operatorname{op}}} X$ , which is equivalent to the homotopy class definition by Exercise 1 of Sheet 7. Since  $\Delta^{\operatorname{op}}$  has a final object [0], it is filtered. Note that over **Set**, small filtered colimits respect finite limits, and therefore we have  $\pi_0(X \times Y) \cong \pi_0(X) \times \pi_0(Y)$  for all simplicial sets X, Y.

## Exercise 2

*Proof.* (1) We begin by considering a commutative diagram

$$\Lambda_k^n \longrightarrow p^{-1}(a) = X_a \longrightarrow X$$

$$\downarrow \qquad \qquad \downarrow p,$$

$$\Delta^n \longrightarrow \Delta^0 \longrightarrow A$$

where  $0 \le k < n$  and the square on the right is a pullback. From the LLP of  $\Lambda_k^n \to \Delta^n$  against p we get a lift  $\Delta^n \to X$  and then, using the universal property of the pullback with respect to the lift and  $\Delta^n \to \Delta^0$ , we get a lift of  $\Lambda_k^n \to \Delta^n$  against  $X_a \to \Delta^0$ .

This implies that  $X_a$  is an  $\infty$ -category, hence we only need to prove that its morphisms are invertible, which will make it a  $\infty$ -groupoid and therefore a Kan complex.

To prove this, for any morphism  $f: x \to y$  in  $X_a$  we consider the diagram

$$\Lambda_0^2 \xrightarrow{(\mathrm{id}_x, f)} X_t$$

$$\downarrow \qquad \qquad \downarrow$$

$$\Lambda_0^2$$

inducing the pictured 2-simplex t by our previous observations. The morphism f is a right inverse of  $d^2(t) = g \colon y \to x$  and from

$$\Lambda_0^2 \xrightarrow{(\mathrm{id}_y, g)} X_a$$

$$\downarrow \qquad \qquad \qquad \downarrow \qquad \qquad \qquad \downarrow$$

$$\Lambda^2$$

we also get a left inverse  $d^2(u) = h$  of g. It follows that g is invertible and the same goes for f.

(2) Let's consider for any morphism  $f: a_0 \to a_1$  in A the commutative diagram

$$\Lambda_0^1 = \Delta^0 \xrightarrow{x_0} X$$

$$\downarrow \qquad \qquad \downarrow^p,$$

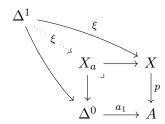

$$\Delta^1 \xrightarrow{f} A$$

which from the LLP of  $\Lambda_0^1 \to \Delta^1$  against p grants us the desired lift  $\phi \colon x_0 \to x_1$  of f along p.

To prove that the equivalence class of  $x_1$  in  $\pi_0(X_{a_1})$  does not depend on the choice of the lift we consider for any other such lift  $\psi \colon x_0 \to y$  the commutative diagram

$$\Lambda_0^2 \xrightarrow{(\psi,\phi)} X 
\downarrow \qquad t \qquad \downarrow p, 
\Delta^2 \xrightarrow[s_0(f)]{} A$$

granting us a 2-simplex t which induces a morphism  $d^0(t) = \xi \colon x_1 \to y$ . The commutative diagram

then shows that this morphism also lies in  $X_a$  through the universal property of the pullback and therefore  $[x_1] = [y]$  in  $\pi_0(X_a)$ .

We have just proven that distinct lifts through p of the same morphism have the same codomain up to equivalence as long as they have the same domain.

(3) Let  $t \colon \Delta^2 \to A$  be the map corresponding to our commutative trangle. We proceed by drawing the commutative diagram

$$\Lambda_1^2 \xrightarrow{(\phi',\phi)} X 
\downarrow \qquad \qquad \downarrow p, 
\Delta^2 \xrightarrow{t} A$$

which by the LLP of  $\Lambda_0^2 \to \Delta^2$  against p grants us a lift  $u: \Delta^2 \to X$  (and therefore a commutative triangle) with  $d^0(u) = \phi'$ ,  $d^1(u) = \psi$ :  $x_0 \to x_2$  and  $d^2(u) = \phi$  such that  $p(\psi) = g$ .

(4) The functor, which we will denote by F, has already been well defined on objects, hence we only need to specify the action on morphisms. We know that for any map  $f: a_0 \to a_1$  in A we have a lift  $\phi: x_0 \to x_1$  such that  $p(\phi) = f$ , thus we define  $F([f]): \pi_0(X_{a_0}) \to \pi_0(X_{a_1})$  as  $F([f])([x_0]) = [x_1]$ , where  $[x_1]$  lies in  $\pi_0(X_{a_1})$  since  $p(d^0(\phi)) = d^0(p(\phi)) = d^0(f) = a_1$ . We need to show that this map is well defined, for which we will start with proving that, after fixing a representative f of [f], if we have a morphism  $\psi: x_0 \to x'_0$  in  $X_{a_0}$  then we also have a morphism  $x_1 \to x'_1$  in  $X_{a_1}$  between the objects specified by the liftings  $\phi$ ,  $\phi'$  of f with domains  $x_0, x'_0$ .

We can construct a map  $(\phi' \cdot \psi, \phi) \colon \Lambda_0^2 \to X$  which, composed with p, gives us  $(p(\phi' \cdot \psi), f) \colon \Lambda_0^2 \to A$ . We want to extend this to a 2-simplex  $t \colon \Delta^2 \to A$  where  $d^0(t) = \mathrm{id}_a$ ; we will then lift it through p thanks to the RLP with respect to  $\Lambda_0^2 \to \Delta^2$ , getting a 2-simplex u in X such that  $d^0(u)$  is by construction the desired morphism  $x_1 \to x_1'$  in  $X_{a_1}$ .

$$\Lambda_0^2 \xrightarrow{(\phi' \cdot \psi, \phi)} X$$

$$\downarrow \qquad \qquad \downarrow \qquad \qquad \downarrow p$$

$$\Delta^2 \xrightarrow{t} A$$

Notice that we have 2-simplices v, v' showing that  $f \cdot \mathrm{id}_a = p(\phi') \cdot p(\psi) \sim p(\phi' \cdot \psi)$ ,  $f \cdot \mathrm{id}_a \sim f$ , thus we may construct a horn  $(s_0(f), v', v) \colon \Lambda_1^3 \to A$  which can be extended to a 3-simplex  $\alpha$  such that  $d^1(\alpha) = t$  is the desired 2-simplex in A.

Having proven that  $F([f])([x_0])$  does not depend on the representative of  $[x_0]$ , we show that it also does not depend on the representative of [f].

Suppose that  $g \in [f]$ , i.e. we have a 2-simplex t in A showing that  $\mathrm{id}_a \cdot f \sim g$ , meaning that  $d^0(t) = \mathrm{id}_a$ ,  $d^1(t) = g$ ,  $d^2(t) = f$ . After choosing lifts  $\phi \colon x_0 \to x_1$ ,  $\psi \colon x_0 \to x_1'$  of f, g through p, we can construct the commutative square

$$\Lambda_0^2 \xrightarrow{(\psi,\phi)} X 
\downarrow \qquad \qquad \downarrow^p, 
\Delta^2 \xrightarrow{t} A$$

where the lift u is such that  $d^0(u) = h$  provides the desired morphism  $x_1 \to x'_1$  in  $X_{a_1}$ . This shows that F([f]) is well defined. We still have to prove that this association is functorial.

If  $[f] = [\mathrm{id}_a]$ , then for any  $[x] \in \pi_0(X_a)$  we may pick  $\mathrm{id}_x$  as a lift of  $\mathrm{id}_a$  through p, which then shows that  $F([\mathrm{id}_a])([x]) = [x]$ .

On the other hand, consider two composable morphisms [f], [g], where  $\mathrm{dom}(f)=a$ . Given a 2-simplex t in A such that  $d^0(t)=g$ ,  $d^1(t)=g\cdot f$ ,  $d^2(t)=f$  and fixed an element  $[x_0]\in\pi_0(X_a)$ , after fixing lifts  $\phi\colon x_0\to x_1,\, \psi\colon x_1\to x_2$  of f,g by (3) we get a 2-simplex u in X such that  $d^0(u)=\psi$ ,  $d^1(u)=\xi\colon x_0\to x_2,\, d^2(u)=\phi$  and  $\xi$  is a lift of  $g\cdot f$  through p with  $\phi\cdot\psi\sim\xi$ . It follows that  $F([g]\cdot[f])=F([g])\cdot F([f])$ .  $\square$
